

identity and sequence similarity is the BLAST algorithm, which is described in Altschul  
*et al.*, *J. Mol. Biol.* 215:403-410 (1990). Software for performing BLAST analyses is  
publicly available through the National Center for Biotechnology Information

~~(<http://www.ncbi.nlm.nih.gov/>)~~. Typically, default program parameters can be used to  
perform the sequence comparison, although customized parameters can also be used. For  
amino acid sequences, the BLASTP program uses as defaults a wordlength (W) of 3, an  
expectation (E) of 10, and the BLOSUM62 scoring matrix (*see* Henikoff & Henikoff,  
*Proc. Natl. Acad. Sci. USA* 89, 10915 (1989))

For purposes of classifying amino acids substitutions as conservative or  
nonconservative, amino acids are grouped as follows: Group I (hydrophobic sidechains):  
norleucine, met, ala, val, leu, ile; Group II (neutral hydrophilic side chains): cys, ser, thr;  
Group III (acidic side chains): asp, glu; Group IV (basic side chains): asn, gln, his, lys,  
arg; Group V (residues influencing chain orientation): gly, pro; and Group VI (aromatic  
side chains): trp, tyr, phe. Conservative substitutions involve substitutions between  
amino acids in the same class. Non-conservative substitutions constitute exchanging a  
member of one of these classes for a member of another.

Therapeutic agents of the invention are typically substantially pure from  
undesired contaminant. This means that an agent is typically at least about 50% w/w  
(weight/weight) purity, as well as being substantially free from interfering proteins and  
contaminants. Sometimes the agents are at least about 80% w/w and, more preferably at  
least 90 or about 95% w/w purity. However, using conventional protein purification  
techniques, homogeneous peptides of at least 99% w/w can be obtained.

Specific binding between two entities means an affinity of at least  $10^6$ ,  $10^7$ ,  
 $10^8$ ,  $10^9$   $M^{-1}$ , or  $10^{10}$   $M^{-1}$ . Affinities greater than  $10^8$   $M^{-1}$  are preferred.

The term "antibody" or "immunoglobulin" is used to include intact  
antibodies and binding fragments thereof. Typically, fragments compete with the intact  
antibody from which they were derived for specific binding to an antigen fragment  
including separate heavy chains, light chains Fab, Fab' F(ab')<sub>2</sub>, Fabc, and Fv. Fragments  
are produced by recombinant DNA techniques, or by enzymatic or chemical separation of  
intact immunoglobulins. The term "antibody" also includes one or more immunoglobulin  
chains that are chemically conjugated to, or expressed as, fusion proteins with other  
proteins. The term "antibody" also includes bispecific antibody. A bispecific or  
bifunctional antibody is an artificial hybrid antibody having two different heavy/light  
chain pairs and two different binding sites. Bispecific antibodies can be produced by a
